## Denying the data: Learning from the accomplished sciences

We stressed to observers that their answers had no bearing on the choices made by the confederate and that the confederate could not hear what was said in the observing room

## Social

Neurocognitive and electrophysiological evidence of altered face processing in parents of children with autism: implications for a model of abnormal development of social brain circuitry in autism. As can be seen in , autistic adults with better observed social skills were rated as less awkward, smarter, and having higher quality interactions, those with better theory of mind performance on the TASIT were rated as smarter, and those with higher emotion recognition scores on the ER-40 were rated less dominant and more awkward.

## Lenses of the Heart: How Actors' and Observers' Perspectives Influence Emotional Experiences

Taken together, findings from this study raise questions about the predictive utility of standalone measures of social abilities in autistic people for understanding their social interaction difficulties with NA people. If so, this process could have adverse consequences for the social experiences of autistic adults, whose differences in social expressivity could be misperceived in ways that reinforce reluctance of NA adults to interact with them. The reward of having drawn a good card, the prospect of winning, the potential regret of overreaching, all are blunted to a detached observer.

## Frontiers

This has started to change in recent years.

## Actor/observer asymmetry in risky decision making

The IOS and SCI are measures of interpersonal closeness that are averaged together to create an overall closeness composite score. Regardless of interpretation, however, this finding of NA social cognition predicting outcomes with autistic partners was not hypothesized and should therefore

be interpreted cautiously until replicated.
